Representing an irrational number on the number line

Therefore we can deduce that :

Each irrational number can be represented by a point on the number line.

Generally

To draw a line segment with length \sqrt{a} length unit where $a > 1$,

draw a right-angled triangle in which

the length of one side of the right-angle = $\frac{a-1}{2}$ length unit

and the length of the hypotenuse = $\frac{a+1}{2}$ length unit.

Example:

Draw a line segment with length $=\sqrt{7}$ length unit, then use it to determine the points which represent the following numbers on the number line :

Using the compasses with a distance equal to

the length of \overline{BC} taking O as a centre

, draw an arc to cut the number line

on the right side of O at the point X,

then X is the point which represents $\sqrt{7}$

Subsets of real numbers (Intervals)

If X is the set of integers which greater than or equal to -3 and less than 2 , we can express the set X by the description method as follows:
 $X = \{a : a \in \mathbb{Z}, -3 \leq a < 2\}$ we can express it by listing method $X = \{-3, -2, -1, 0, 1\}$
 If $K = \{a : a \in \mathbb{R}, -3 \leq a < 2\}$ but it is impossible to express the set K by listing method because there are an infinity of real numbers between -3 and 2 . So we use another method to express a subset of the set of real numbers, which is (the intervals).

Operations on the real numbers

We know that $2x$ and $3x$ are two like algebraic terms, then $2x + 3x = 5x$ then we deduce that $2\sqrt{5} + 3\sqrt{5} = (2+3)\sqrt{5} = 5\sqrt{5}$, but $2x$ and $3y$ are two unlike algebraic terms then their sum $2x + 3y$ then the sum of $2\sqrt{3}, 3\sqrt{2}$ written in the form $2\sqrt{3} + 3\sqrt{2}$

Properties of addition of real numbers

Closure :

For every $a \in \mathbb{R}$ and $b \in \mathbb{R}$ we find that $(a + b) \in \mathbb{R}$

i.e. The sum of any two real numbers is a real number, therefore we say \mathbb{R} is closed under addition operation.

For example :

• $\sqrt{5} \in \mathbb{R}$ and $2\sqrt{5} \in \mathbb{R}$ we find that : $\sqrt{5} + 2\sqrt{5} = 3\sqrt{5} \in \mathbb{R}$

Commutative property :

For every $a \in \mathbb{R}$ and $b \in \mathbb{R}$ it will be $a + b = b + a$

For example :

$$5\sqrt[3]{2} + 4\sqrt[3]{2} = 9\sqrt[3]{2} \quad , \quad 4\sqrt[3]{2} + 5\sqrt[3]{2} = 9\sqrt[3]{2}$$

i.e. $5\sqrt[3]{2} + 4\sqrt[3]{2} = 4\sqrt[3]{2} + 5\sqrt[3]{2}$

Associative property :

For every $a \in \mathbb{R}$, $b \in \mathbb{R}$ and $c \in \mathbb{R}$ it will be $(a + b) + c = a + (b + c) = a + b + c$

For example :

$$(\sqrt{3} + 2\sqrt{3}) + 5\sqrt{3} = 3\sqrt{3} + 5\sqrt{3} = 8\sqrt{3} \quad ,$$

$$\sqrt{3} + (2\sqrt{3} + 5\sqrt{3}) = \sqrt{3} + 7\sqrt{3} = 8\sqrt{3}$$

i.e. $(\sqrt{3} + 2\sqrt{3}) + 5\sqrt{3} = \sqrt{3} + (2\sqrt{3} + 5\sqrt{3})$

The additive neutral :

For every $a \in \mathbb{R}$ it will be $a + 0 = 0 + a = a$

i.e. Zero is the additive neutral.

For example : $\sqrt{2} + 0 = 0 + \sqrt{2} = \sqrt{2} \quad , \quad -\sqrt[3]{5} + 0 = 0 + (-\sqrt[3]{5}) = -\sqrt[3]{5}$

The additive inverse of every real number :

For every $a \in \mathbb{R}$ there is $(-a) \in \mathbb{R}$ where $a + (-a) = \text{zero}$ (the additive neutral)

For example :

- The additive inverse of the number $\sqrt{3}$ is $-\sqrt{3}$ and vice versa because $\sqrt{3} + (-\sqrt{3}) = 0$
- The additive inverse of the number $2 + \sqrt{5}$ is $-(2 + \sqrt{5})$ and equals $-2 - \sqrt{5}$
- The additive inverse of the number $3 - \sqrt{2}$ is $-(3 - \sqrt{2})$ and equals $\sqrt{2} - 3$
- The additive inverse of the number zero is itself.

[1] Find the result of each of the following in the simplest form:

(1)	$\sqrt{3} + 2\sqrt{3}$
(2)	$3\sqrt{2} - 5\sqrt{2}$
(3)	$2\sqrt{5} - 3\sqrt{5} + \sqrt{5}$
(4)	$5^3\sqrt{7} - 8^3\sqrt{7} + 2^3\sqrt{7}$
(5)	$4\sqrt{5} - 2\sqrt{5} + 5\sqrt{5} - \sqrt{5}$
(6)	$5\sqrt{3} - 7\sqrt{3} + 3\sqrt{3} - \sqrt{3}$
(7)	$\sqrt{5} - \sqrt{3} + 2\sqrt{5} + \sqrt{3}$
(8)	$2\sqrt{3} + 5 + \sqrt{3} - 6$
(9)	$2\sqrt{7} - 3\sqrt{2} + \sqrt{7} + 5\sqrt{7}$
(10)	$2\sqrt{2} - 3^3\sqrt{2} + 5\sqrt{2} + \sqrt{2}$
(11)	$8\sqrt{\frac{1}{4}} + 2^3\sqrt{3} - \sqrt[3]{64} - 5^3\sqrt{3}$
(12)	$\frac{1}{4}\sqrt{2} + \frac{2}{7}\sqrt{5} + \frac{3}{4}\sqrt{2} - \frac{2}{7}\sqrt{5}$

The properties of multiplication operation of real numbers

Closure :

For every $a \in \mathbb{R}$ and $b \in \mathbb{R}$ it will be $a \times b \in \mathbb{R}$

i.e. The product of any two real numbers is a real number therefore we say :

The multiplication operation is closed in \mathbb{R}

For example :

$$\bullet \sqrt{3} \in \mathbb{R} \text{ and } 2\sqrt{3} \in \mathbb{R}$$

$$\text{We find that : } \sqrt{3} \times 2\sqrt{3} = 2 \times 3 = 6 \in \mathbb{R}$$

Commutative property :

For every $a \in \mathbb{R}$ and $b \in \mathbb{R}$ it will be $a \times b = b \times a$

For example :

$$\bullet 2\sqrt{5} \times 3\sqrt{5} = 6 \times 5 = 30, 3\sqrt{5} \times 2\sqrt{5} = 6 \times 5 = 30$$

$$\text{i.e. } 2\sqrt{5} \times 3\sqrt{5} = 3\sqrt{5} \times 2\sqrt{5}$$

The associative property :

For every $a \in \mathbb{R}$, $b \in \mathbb{R}$ and $c \in \mathbb{R}$ it will be $(a \times b) \times c = a \times (b \times c) = a \times b \times c$

For example :

$$\bullet (2\sqrt{7} \times 4\sqrt{7}) \times \sqrt{7} = 56 \times \sqrt{7} = 56\sqrt{7}$$

$$\bullet 2\sqrt{7} \times (4\sqrt{7} \times \sqrt{7}) = 2\sqrt{7} \times 28 = 56\sqrt{7}$$

$$\text{i.e. } (2\sqrt{7} \times 4\sqrt{7}) \times \sqrt{7} = 2\sqrt{7} \times (4\sqrt{7} \times \sqrt{7})$$

The multiplicative neutral :

For every $a \in \mathbb{R}$ it will be $a \times 1 = 1 \times a = a$

i.e. One is the multiplicative neutral in \mathbb{R}

For example :

$$\bullet \sqrt[3]{5} \times 1 = 1 \times \sqrt[3]{5} = \sqrt[3]{5}$$

The multiplicative inverse of any non-zero real number :

For every real number $a \neq 0$, there is a real number $\frac{1}{a}$ where $a \times \frac{1}{a} = 1$ which is the multiplicative neutral.

For example :

- The multiplicative inverse of $\sqrt{3}$ is $\frac{1}{\sqrt{3}}$
because $\sqrt{3} \times \frac{1}{\sqrt{3}} = 1$
- The multiplicative inverse of $-\frac{\sqrt{2}}{5}$ is $-\frac{5}{\sqrt{2}}$
- The multiplicative inverse of the number 1 is itself and also the multiplicative inverse of -1 is itself.

Notice that :

Both the number and its multiplicative inverse have the same sign.

Notice that :

There is no multiplicative inverse for the number zero because $\frac{1}{\text{zero}}$ is meaningless (**i.e.** undefined)

Remark

- Since each non-zero real number has a multiplicative inverse then the division operation by any real number does not equal zero is possible in \mathbb{R} and it is defined as
For every $a \in \mathbb{R}$ and $b \in \mathbb{R}^*$ it will be $a \div b = a \times \frac{1}{b}$
i.e. The division operation ($a \div b$) means multiplying the number a by the multiplicative inverse of the number b such that $b \neq 0$

Then we can deduce that :

The division operation in \mathbb{R} is not commutative and it is not associative.

Distributing multiplication on addition and subtraction

For any three real numbers a , b and c it will be :

- $a(b \pm c) = ab \pm ac$
- $(b \pm c)a = ba \pm ca$

Remarks:

- $(a+b)(a-b) = a^2 - b^2$

For example :

$$\bullet \sqrt{3} \times \sqrt{12} = \sqrt{36} = 6$$

$$\bullet \sqrt{50} = \sqrt{25 \times 2} = \sqrt{25} \times \sqrt{2} = 5\sqrt{2}$$

$$2 \quad \frac{\sqrt{a}}{\sqrt{b}} = \sqrt{\frac{a}{b}} \text{ where } b \neq 0$$

For example :

$$\bullet \frac{\sqrt{8}}{\sqrt{2}} = \sqrt{\frac{8}{2}} = \sqrt{4} = 2$$

$$\bullet \frac{\sqrt{\frac{16}{49}}}{\sqrt{\frac{16}{49}}} = \frac{\sqrt{16}}{\sqrt{49}} = \frac{4}{7}$$

$$3 \quad \frac{\sqrt{a}}{\sqrt{b}} = \frac{\sqrt{a}}{\sqrt{b}} \times \frac{\sqrt{b}}{\sqrt{b}} = \frac{\sqrt{ab}}{b} \text{ where } b \neq 0$$

$$\bullet \frac{\sqrt{2}}{\sqrt{5}} = \frac{\sqrt{2}}{\sqrt{5}} \times \frac{\sqrt{5}}{\sqrt{5}} = \frac{\sqrt{10}}{5}$$

The two conjugate numbers

If a and b are two positive rational numbers , then each of the two numbers

$(\sqrt{a} + \sqrt{b})$ and $(\sqrt{a} - \sqrt{b})$ is conjugate to the other one and we find that

- Their sum = $(\sqrt{a} + \sqrt{b}) + (\sqrt{a} - \sqrt{b}) = 2\sqrt{a}$ = twice the first term.
- Their product = $(\sqrt{a} + \sqrt{b})(\sqrt{a} - \sqrt{b}) = (\sqrt{a})^2 - (\sqrt{b})^2 = a - b$

- The difference:

Greater – smaller = $(\sqrt{a} + \sqrt{b}) - (\sqrt{a} - \sqrt{b}) = 2\sqrt{b}$ (twice the second term)

Smaller – greater = $(\sqrt{a} - \sqrt{b}) - (\sqrt{a} + \sqrt{b}) = -2\sqrt{b}$ (negative twice the second term)

Example: $(\sqrt{2} + \sqrt{5})$ its conjugate is $(\sqrt{2} - \sqrt{5})$

Their sum 2 of 1 st term	G - S 2 of 2 nd term	S - G -2 of 2 nd term	Their product $(1^{st})^2 - (2^{nd})^2$
$2\sqrt{2}$	$2\sqrt{5}$	$-2\sqrt{5}$	$2 - 5 = -3$

Relation between two variables

Islam has 50 pounds. If Islam went to the playhouse, he would find two kinds of favourite games :

- The first kind costs 5 pounds for the game each time.
- The second kind costs 10 pounds for the game each time.
- Assume that the number of times that he will play the first kind of games is x and of the second kind is y
- Then, the cost of playing the first game is $5x$ pounds and the cost of playing the second game is $10y$ pounds.
- In order to spend all his money, it should be : $5x + 10y = 50$

We can simplify the previous relation by dividing all terms by 5 to get an equivalent equation which is $x + 2y = 10$ it can be written also in the form : $2y = 10 - x$

$$y = \frac{10 - x}{2}$$

If Islam decided that he will not play the first kind.

$$x = 0, \text{ then } y = \frac{10 - 0}{2} = 5$$

If he decided to play two times of the first kind

$$x = 2, \text{ then } y = \frac{10 - 2}{2} = 4$$

Slope of straight line

If a point moves on a straight line L from the location $A (x_1, y_1)$ to the location

$B (x_2, y_2)$, then :

The change in the x -coordinates = $x_2 - x_1$

It is called (the horizontal change).

The change in the y -coordinates = $y_2 - y_1$

It is called (the vertical change).

The ratio of the change in the y -coordinates to the change in the x -coordinates is called the slope of the straight line (m).

The slope of the straight line = $\frac{\text{the change in } y\text{-coordinates}}{\text{the change in } x\text{-coordinates}} = \frac{\text{the vertical change}}{\text{the horizontal change}}$

i.e. $S = \frac{y_2 - y_1}{x_2 - x_1}$, where $x_1 \neq x_2$, S is undefined if $x_1 = x_2$

Sheet (14)

The ascending and descending cumulative frequency table and their graphical representation

Sheet (14)
The ascending and descending cumulative frequency table and their graphical representation**Example 1**

The following frequency table shows the weekly wages in pounds of 50 workers in one factory :

Sets of wages	54 –	58 –	62 –	66 –	70 –	Total
No. of workers (Frequency)	5	12	22	7	4	50

Form the ascending cumulative frequency table and represent it graphically , then find :

- 1 The number of workers whose weekly wages are less than 60 pounds.
- 2 The percentage of the number of workers whose weekly wages are less than 60 pounds.

Solution

- Form the ascending cumulative frequency table as follows :

The upper boundaries of sets	Frequency	Sets of wages	54 –	58 –	62 –	66 –	70 –
Less than 54	zero	Number of workers (Frequency)	5	12	22	7	4
Less than 58	5	Less than 54 = 0					
Less than 62	17	Less than 58 = 5 + 0 = 5					
Less than 66	39	Less than 62 = 5 + 12 = 17					
Less than 70	46	Less than 66 = 5 + 12 + 22 = 39					
Less than 74	50	Less than 70 = 5 + 12 + 22 + 7 = 46					
		Less than 74 = 5 + 12 + 22 + 7 + 4 = 50					

The ascending cumulative frequency table.

Notice that : The ascending cumulative frequency begins with zero and ends at the total frequency. To represent the ascending cumulative frequency table graphically , do as follows :

- 1 Specialize the horizontal axis for sets and the vertical axis for the ascending cumulative frequency.
- 2 Choose a suitable scale to represent data on the vertical axis so that it contains the ascending cumulative frequency easily.
- 3 Represent the ascending cumulative frequency of each set , then draw the graph (the curve) such that it passes through the points which we located as shown in the opposite figure.

• From the graph , we find that :

- 1 The number of workers whose weekly wages are less than 60 pounds = 10 workers.
- 2 The percentage of the number of workers whose weekly wages are less than 60 pounds = $\frac{10}{50} \times 100\% = 20\%$

Example 2

The following frequency table shows the weekly wages of 50 workers in one factory :

Sets of wages	54 –	58 –	62 –	66 –	70 –	Total
No. of workers (Frequency)	5	12	22	7	4	50

Form the descending cumulative frequency table and represent it graphically , then find :

- 1 The number of workers whose weekly wages are 60 pounds or more.
- 2 The percentage of the number of workers whose weekly wages are 60 pounds or more.

Solution

- Form the descending cumulative frequency table as follows :

Sets of wages	54 –	58 –	62 –	66 –	70 –
Number of workers (Frequency)	5	12	22	7	4

54 and more =	5 + 12 + 22 + 7 + 4 = 50
58 and more =	12 + 22 + 7 + 4 = 45
62 and more =	22 + 7 + 4 = 33
66 and more =	7 + 4 = 11
70 and more =	4
74 and more =	0

The lower boundaries of sets	Frequency
54 and more	50
58 and more	45
62 and more	33
66 and more	11
70 and more	4
74 and more	zero

The descending cumulative frequency table

Notice that : The descending cumulative frequency begins with the total frequency and ends with zero.

- To represent this table graphically , follow the same previous steps in the ascending cumulative frequency table to get the opposite graph.

- From the graph , we find that :

- 1 The number of workers whose weekly wages are 60 pounds or more = 40 workers.

- 2 The percentage of those workers = $\frac{40}{50} \times 100\% = 80\%$

The descending cumulative frequency curve

Remark

we can graph the two curves of the ascending and descending cumulative frequency of a frequency distribution in one sketch as shown in the opposite graph.

Sheet (15)

The Mean

Remember that :

To calculate the mean of a set of values, do as follows :

- 1 Find the sum of these values.
- 2 Divide this sum by the number of these values

i.e. The mean of a set of values = $\frac{\text{The sum of values}}{\text{Number of values}}$

For example:

If the marks of 5 students are 25 , 23 , 21 , 22 , 24

, then the mean of marks = $\frac{25 + 23 + 21 + 22 + 24}{5} = 23$ marks.

Notice that : $23 \times 5 = 115$

, the sum of marks of the 5 students = $25 + 23 + 21 + 22 + 24 = 115$

i.e. The mean is the value which is given to each item of a set , then the sum of these new values is the same sum of the original values.

Finding the mean of data from the frequency table with sets

Example The following table shows the distribution of the marks of 50 students in mathematics :

Sets	10 –	20 –	30 –	40 –	50 –	Total
Frequency	8	12	14	9	7	50

Find the mean of these marks.

- 1 Determine the centres of sets according to the rule :

The centre of a set = $\frac{\text{the lower limit} + \text{the upper limit}}{2}$

, then the centre of the first set = $\frac{10 + 20}{2} = 15$

, the centre of the second set = $\frac{20 + 30}{2} = 25$... and so on.

Since the lengths of the subsets are equal and each of them = 10 therefore we consider the upper limit of the last set = 60

, then its centre = $\frac{50 + 60}{2} = 55$

2 Form the vertical table :

Set	Centre of the set « X »	Frequency « f »	$X \times f$
10 –	15	8	120
20 –	25	12	300
30 –	35	14	490
40 –	45	9	405
50 –	55	7	385
Total		50	1700

3 The mean = $\frac{\text{The sum of } (X \times f)}{\text{The sum of } f} = \frac{1700}{50} = 34$ marks.

Sheet (16)

The Median

Remember that

The median is the middle value in a set of values after arranging it ascendingly or descendingly. such that the number of values which are less than it is equal to the number of values which are greater than it.

- To find the median of a set of values , we do as follows :

We arrange the values ascendingly or descendingly

If the values number is odd , then

The median is the value lying in the middle exactly.

For example :

If the values are
42 , 23 , 17 , 30 and 20

We arrange them ascendingly as follows

17 , 20 , 23 , 30 , 42

The median = 23

If the values number is even , then

The median

= $\frac{\text{The sum of the two values lying in the middle}}{2}$

For example :

If the values are
27 , 13 , 23 , 24 , 13 , 21

We arrange them ascendingly as follows

13 , 13 , 21 , 23 , 24 , 27

The median = $\frac{21 + 23}{2} = 22$

Finding the median of a frequency distribution with sets graphically

Example The following table shows the frequency distribution of marks of 50 students in math exam :

Sets of marks	0 –	10 –	20 –	30 –	40 –	50 –	Total
Number of students	2	5	8	19	14	2	50

Find the median mark of the student.

Solution

Using the ascending cumulative frequency curve :

The upper boundaries of sets	Frequency
Less than 0	0
Less than 10	2
Less than 20	7
Less than 30	15
Less than 40	34
Less than 50	48
Less than 60	50

Using the descending cumulative frequency curve :

The lower boundaries of sets	Frequency
0 and more	50
10 and more	48
20 and more	43
30 and more	35
40 and more	16
50 and more	2
60 and more	0

\therefore The order of the median = $\frac{50}{2} = 25$

\therefore From the two previous graphs , the median = 36 approximately

Sheet (17)

The Mode

Remember that

The mode of a set of values is the most common value in the set, or in other words, it is the value which is repeated more than any other values.

For example :

The mode of the set of the values : 7 , 3 , 4 , 1 , 7 , 9 , 7 , 4 is 7

Finding the mode for a frequency distribution with equal sets in range.

The following is an example which shows how to find the mode of a frequency distribution with sets.

Example

The following is the frequency distribution of marks of 100 pupils in one of the exams :

Set of marks	10 –	20 –	30 –	40 –	50 –	Total
Number of pupils	16	24	30	20	10	100

Find the mode mark for these pupils.

Solution

We can find the mode of that distribution graphically using the histogram as follows :

- 1 Draw two orthogonal axes : one of them is horizontal and the other is vertical to represent the frequency of each set.
- 2 Divide the horizontal axis into a number of equal parts with a suitable drawing scale to represent the sets.
- 3 Divide the vertical axis into a number of equal parts with a suitable drawing scale to represent the greatest frequency in the sets.
- 4 Draw a rectangle whose base is set (10 –) and its height equals the frequency (16)
- 5 Draw a second rectangle adjacent to the first one whose base is set (20 –) and its height equals the frequency (24)

Sheet (1)

Medians of triangle

Definition

The median of a triangle is the line segment drawn from any vertex of this triangle to the midpoint of the opposite side of this vertex.

For example:

In the opposite figure :

If D is the midpoint of \overline{BC}

, then \overline{AD} is a median of $\triangle ABC$

Notice that :

Any triangle has three medians.

Theorem 1

The medians of a triangle are concurrent.

For example:

In the opposite figure :

\overline{AD} , \overline{BF} and \overline{CE} are the three medians of $\triangle ABC$,

and they are concurrent at M

(i.e. $\overline{AD} \cap \overline{BF} \cap \overline{CE} = \{M\}$)

Theorem 2

The point of concurrence of the medians of the triangle divides each median in the ratio of 1 : 2 from its base.

For example:

In the opposite figure :

In $\triangle ABC$, M is the point of concurrence of its medians , then :

1 $MD = \frac{1}{2} AM$

If $AM = 6$ cm. , then $MD = 3$ cm.

2 $CM = 2 FM$

If $FM = 4$ cm. , then $CM = 8$ cm.

Remark

The point of concurrence of the medians of the triangle divides each of them in the ratio of 2 : 1 from the vertex.

Fact

The point which divides the median in a triangle by the ratio of 1 : 2 from the base is the point of intersection of the medians of this triangle.

In the opposite figure :

If \overline{AD} is a median in $\triangle ABC$ and $M \in \overline{AD}$ such that $AM = 2 MD$,
then M is the point of intersection of the medians of $\triangle ABC$

Theorem 3

In the right-angled triangle, the length of the median from the vertex of the right angle equals half the length of the hypotenuse.

For example:

In the opposite figure :

$\triangle ABC$ is a right-angled triangle at B ,

D is the midpoint of \overline{AC} and $AC = 10$ cm. ,

then $DB = 5$ cm.

The converse of theorem 3

If the length of the median drawn from a vertex of a triangle equals half the length of the opposite side to this vertex, then the angle at this vertex is right.

For example:

In the opposite figure :

If \overline{BD} is a median in $\triangle ABC$,

$BD = 3$ cm. and $AC = 6$ cm. ,

then $m(\angle ABC) = 90^\circ$ "because $BD = \frac{1}{2} AC$ "

Corollary

The length of the side opposite to the angle of measure 30° in the right-angled triangle equals half the length of the hypotenuse.

i.e.

In the opposite figure :

If $\triangle ABC$ is right-angled at B and

$m(\angle C) = 30^\circ$, then $AB = \frac{1}{2} AC$

For example:

If $AC = 20$ cm. , then $AB = 10$ cm.

Remark

The right-angled triangle whose measures of angles are 30° , 60° and 90° is called thirty and sixty triangle.

The isosceles triangle

Triangles are classified according to the lengths of their sides into three types which are :

1 Scalene triangle.

$$AB \neq BC \neq CA$$

2 Isosceles triangle.
(two sides are congruent).

$$DE = DF$$

3 Equilateral triangle.
(three sides are congruent).

$$XY = YZ = ZX$$

And in the following we will study the relations between the angles in the isosceles triangle and the equilateral triangle.

The isosceles triangle theorem

Theorem 1

The base angles of the isosceles triangle are congruent.

For example:

In the opposite figure :

If ABC is a triangle in which :

$$AB = AC, m(\angle A) = 40^\circ,$$

$$\text{then } m(\angle B) = m(\angle C) = \frac{180^\circ - 40^\circ}{2} = 70^\circ$$

Remarks

- Both of the base angles in the isosceles triangle are acute.
- The vertex angle in the isosceles triangle may be acute, right or obtuse angle.

Corollary

If the triangle is equilateral, then it is equiangular where each angle measure is 60°

For example:

In the opposite figure :

If XYZ is a triangle in which

$$XY = YZ = ZX ,$$

$$\text{then } m(\angle X) = m(\angle Y) = m(\angle Z) = 60^\circ$$

Corollaries of the isosceles triangle theorems

Corollary 1

The median of an isosceles triangle from the vertex angle bisects it and is perpendicular to the base.

In the opposite figure :

ABC is a triangle in which $AB = AC$ and

\overline{AD} is a median , then :

1 \overline{AD} bisects $\angle BAC$

i.e. $m(\angle BAD) = m(\angle CAD)$

2 $\overline{AD} \perp \overline{BC}$

**Corollary 2**

The bisector of the vertex angle of an isosceles triangle bisects the base and is perpendicular to it.

In the opposite figure :

ABC is a triangle in which $AB = AC$ and

\overline{AD} bisects $\angle BAC$, then :

1 D is the midpoint of \overline{BC}

i.e. $BD = CD$

2 $\overline{AD} \perp \overline{BC}$

**Corollary 3**

The straight line drawn passing through the vertex angle of an isosceles triangle perpendicular to the base bisects each of the base and the vertex angle.

In the opposite figure :

ABC is a triangle in which $AB = AC$ and

$\overline{AD} \perp \overline{BC}$, then :

1 D is the midpoint of \overline{BC}

i.e. $BD = CD$

2 $m(\angle BAD) = m(\angle CAD)$

Notice that :

The previous three corollaries can be proved using the congruence of $\triangle ABD$ and $\triangle ACD$

Axis of symmetry of a line segment

Definition

The straight line perpendicular to a line segment at its middle is called the axis of symmetry for that line segment , in brief it is known as the axis of a line segment.

In the opposite figure :

If the straight line $L \perp \overline{AB}$ and $C \in$ the straight line L where C is the midpoint of \overline{AB} , then the straight line L is called the axis of \overline{AB}

Property

Any point on the axis of symmetry of a line segment is at equal distances from its terminals (end points).

In the opposite figure :

If the straight line L is the axis of \overline{AB} ,
 $D \in L$, $E \in L$ and $F \in L$, then
 $DA = DB$, $EA = EB$ and $FA = FB$

The converse of the previous property is true

i.e. If a point is at equal distances from the two terminals of a line segment , then this point lies on the axis of this line segment.

In the opposite figure :

If C is a point such
 that $CA = CB$, then
 the point C lies on the axis of \overline{AB}

Axis of symmetry of the isosceles triangle

The isosceles triangle has one axis of symmetry.

It is the straight line drawn from the vertex angle perpendicular to its base.

For example:

If ABC is an isosceles triangle where
 $AB = AC$ and $\overrightarrow{AD} \perp \overline{BC}$, then
 \overrightarrow{AD} is called the axis of symmetry
 of the isosceles triangle ABC

Remarks

- 1 The equilateral triangle has three axes of symmetry, they are the three perpendiculars drawn from its vertices to the opposite sides.

In the opposite figure :

The straight lines L_1 , L_2 and L_3 are the axes of symmetry of the equilateral triangle ABC

- 2 The scalene triangle has no axes of symmetry.

Comparing the lengths of sides in a triangle

Theorem

In a triangle , if two angles are unequal in measure , then the greater angle in measure is opposite to a side greater in length than that opposite to the other angle.

Corollaries**Corollary 1**

In the right-angled triangle , the hypotenuse is the longest side.

In the opposite figure :

If $\triangle ABC$ is right-angled at B , then $m(\angle B) > m(\angle A)$,
 $m(\angle B) > m(\angle C)$ because $\angle B$ is a right angle and each of
 $\angle A$ and $\angle C$ is acute , so we find that :

$AC > BC$ and $AC > AB$ (according to the previous theorem).

Notice that :

In the obtuse-angled triangle, the side opposite to the obtuse angle is the longest side in the triangle.

Corollary 2

The length of the perpendicular line segment drawn from a point outside a straight line to this line is shorter than any line segment drawn from this point to the given straight line.

In the opposite figure :

If $C \notin \overleftrightarrow{AB}$ and $D \in \overleftrightarrow{AB}$ such that $\overline{CD} \perp \overleftrightarrow{AB}$,
 then \overline{CB} is the hypotenuse in $\triangle CBD$
 which is right-angled at D ,

\overline{CA} is the hypotenuse in $\triangle CDA$ which is right-angled at D and so on ...

According to corollary 1 , we find that $CB > CD$, $CA > CD$ and so on ...

i.e. $CD < CB$ and $CD < CA$

**Definition**

The distance between any point and a given straight line is the length of the perpendicular line segment drawn from this point to the given line.

Triangle inequality

Generally

In any triangle , the sum of the lengths of any two sides is greater than the length of the third side.

Generally

In any triangle , the sum of the lengths of any two sides is greater than the length of the third side.

i.e. In any triangle such as $\triangle ABC$

, we get : $AB + BC > AC$

, $BC + CA > AB$

, $CA + AB > CB$

Corollary

The length of any side in a triangle is greater than the difference between the lengths of the other two sides and less than their sum.

And you can prove that from the triangle inequality as follows :

In any triangle ABC :

$$AC + AB > BC \quad (1)$$

$$, \therefore AB + BC > AC \quad \text{i.e. } BC > AC - AB \quad (2)$$

From (1) and (2) , we deduce that : $AC - AB < BC < AC + AB$

Remark

To check the possibility that three lengths can be side lengths of a triangle , do as follows :

Compare the greatest length with the sum of the other two lengths :

- If the greatest length is greater than or equal to the sum of the other two lengths , you deduce that the three given lengths couldn't be lengths of the three sides of a triangle. (i.e. no triangle could be drawn with these side lengths).
- If the greatest length is less than the sum of the other two lengths , you deduce that the three given lengths could be lengths of the three sides of a triangle. (i.e. a triangle could be drawn with these side lengths).
